Proterozoic

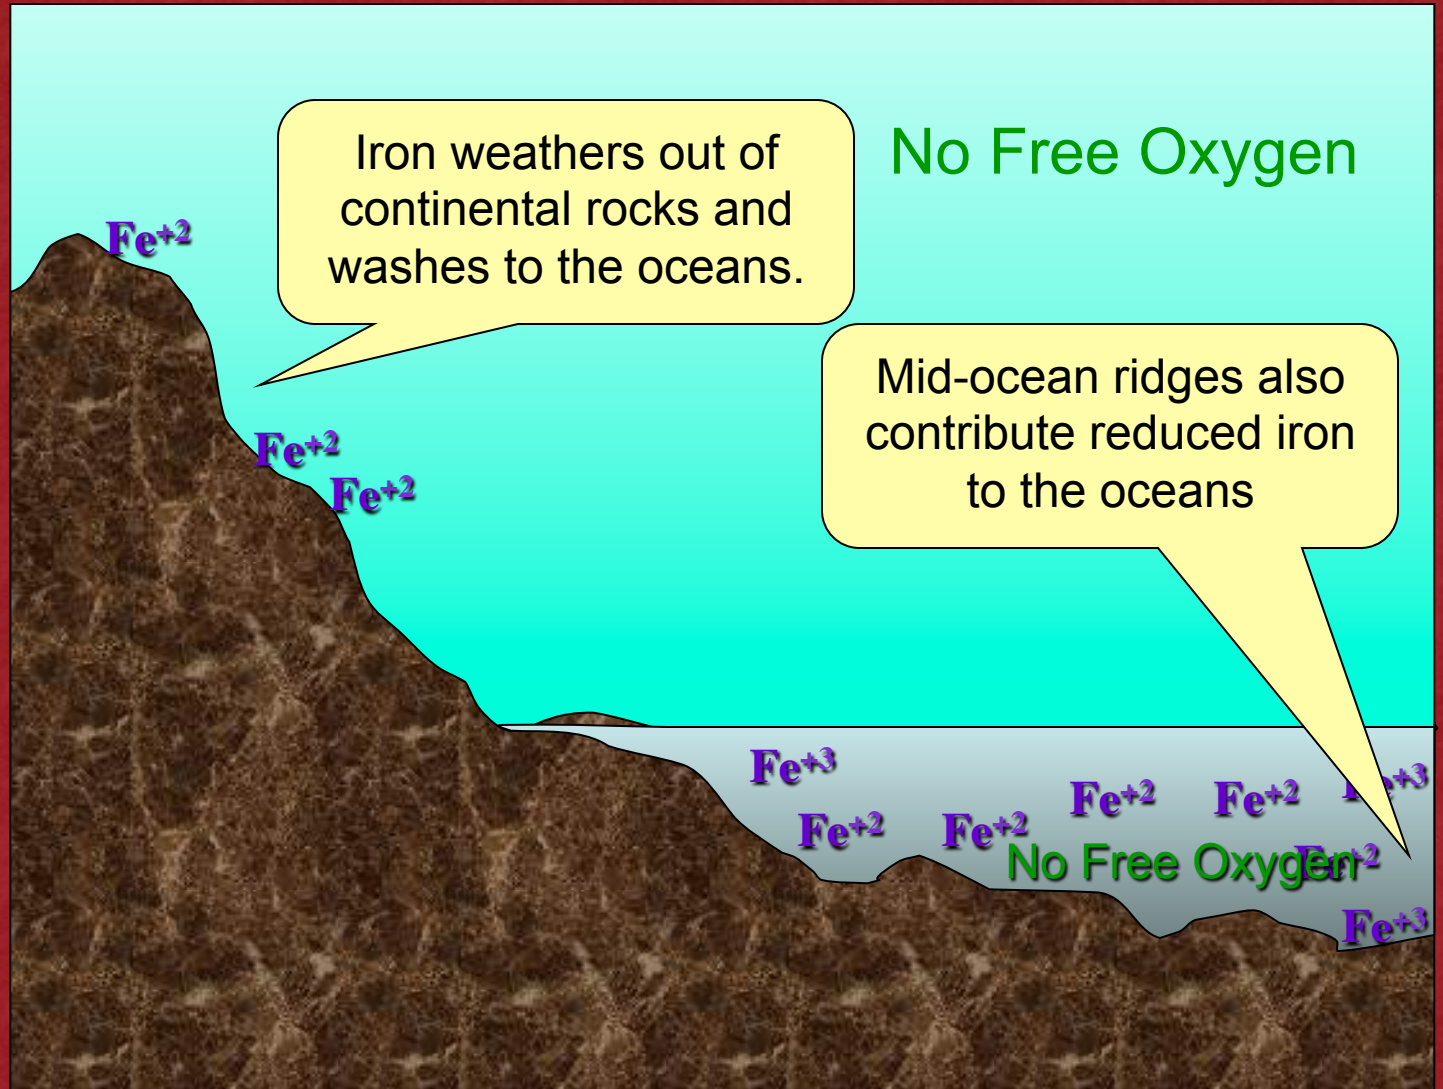

The Proterozoic

*~2,500,000,000 – 540,000,000 years ago
(2.5 – 0.54 Ga)*

- Free oxygen builds up in shallow oceans, then atmosphere
- Massive banded iron deposited (2.5-1.8 Ga)
- First good body fossils of complex, multicellular animals (Vendian, 650-540 Ma)
- Probable ancestors of some animal phyla identified

Eventually, most of the dissolved iron precipitates out of sea water, stopping BIF formation and allowing the oxygen to escape into the atmosphere.

Free oxygen in the atmosphere bonds with iron weathering out of continental rocks, forming red beds.

BIF in oceans

Redbeds on land

FIGURE 5.10
Model for the growth of oxygen in Earth's atmosphere. I, II, and III are stages in atmosphere evolution. Also shown are the time relationships of various oxygen-recording sediments and organisms as discussed in the text.

<http://earth.usc.edu/~geol150/evolution/precambrian2.html>

<http://earth.usc.edu/~stott/Catalina/Earlyatmosphere.html>

Global Increase in Oxygen

The increase in atmospheric oxygen caused a major turning point in Earth's history.

- Once the reduced iron sink was consumed, oxygen became one of the most abundant gases in the atmosphere. Surface and oceanic chemistry changed dramatically from primarily reducing to predominantly oxidizing.
- The effect on life can not be underestimated - the dominant mode of metabolism on Earth changed from anaerobic to aerobic. Oxygen is a highly efficient oxidizer of organic matter, and the switch in metabolism may be responsible for the great diversification of macroscopic life that would follow. It was a disaster for the dominant life forms of the time.

The Earth would never be the same as it was

Global Increase in Oxygen

As the amount of atmospheric oxygen increased through the Proterozoic, new living systems evolved.

- Eukaryotic organisms became more diverse and abundant. There was also an increase in eukaryote body size, with large (>1m) eukaryotes becoming abundant in the late Proterozoic.
- Eukaryotes diversified into both new and pre-existing ecologic niches, and created brand new kinds of ecosystems.
- By the end of the Proterozoic, the ancestral taxa of several major animal groups became recognizable.

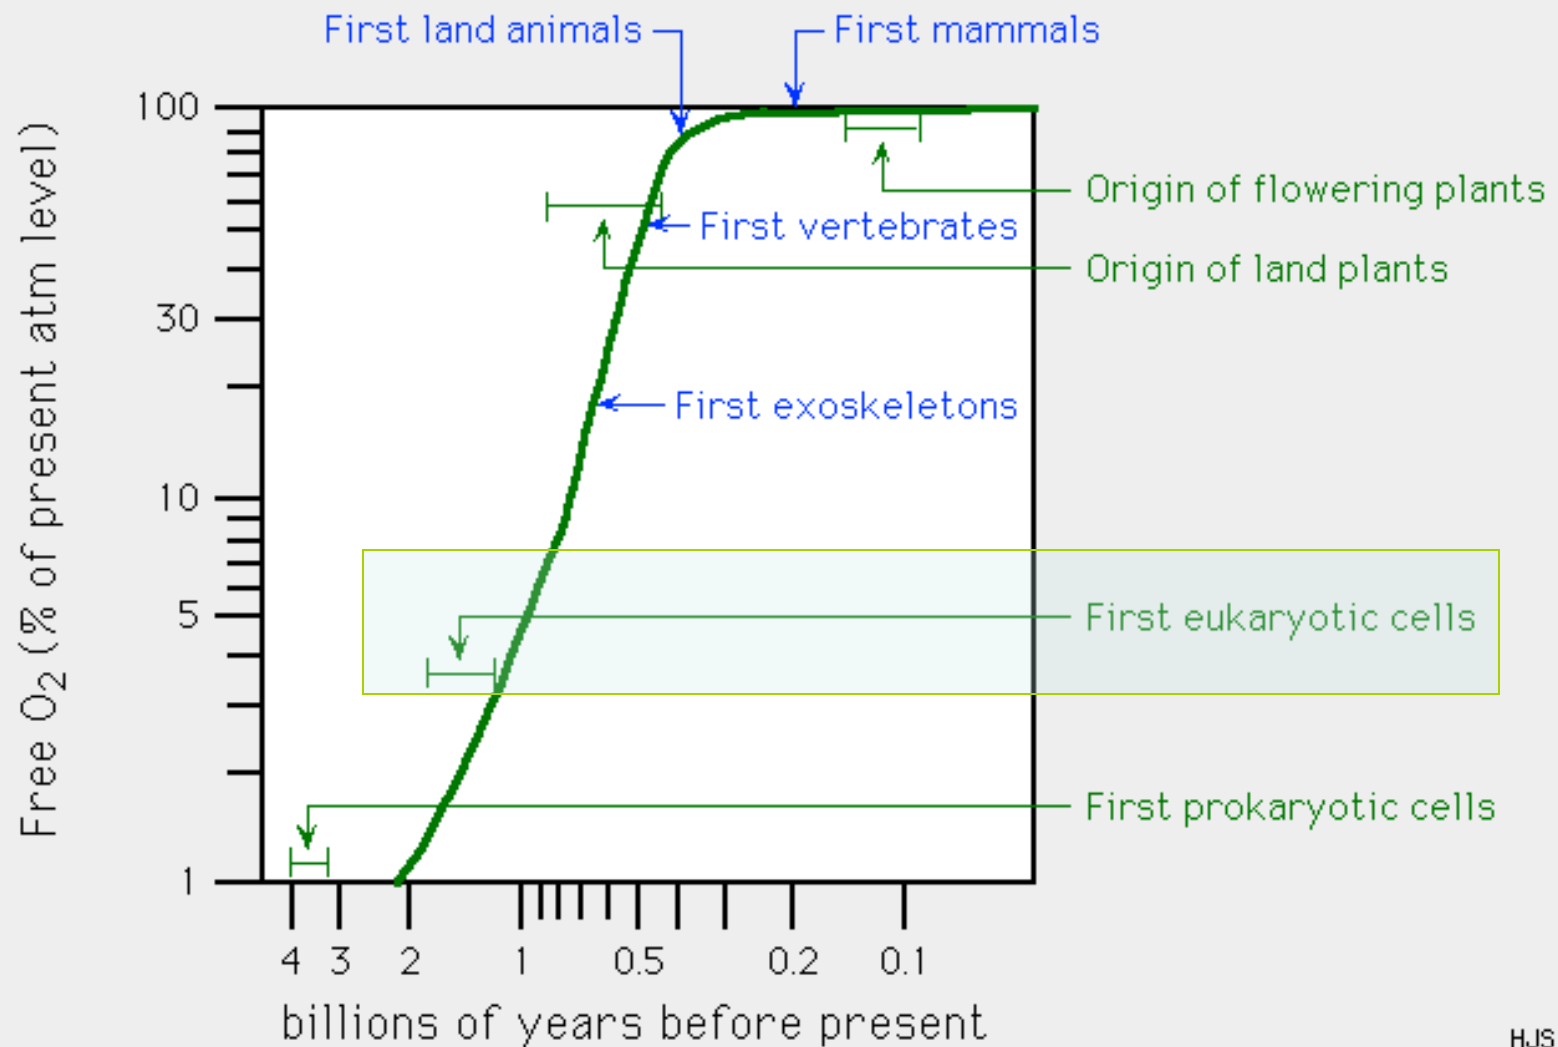

What would Earth be like without life?

Venus does not have Earth-like life. We can infer what Earth would be like without life by comparing Earth's atmospheric composition to Venus's.

| <u>Gas</u> | <u>Venus</u> | <u>Earth w/life</u> | <u>Earth w/o life</u> |
|-----------------|--------------|---------------------|-----------------------|
| CO ₂ | 95% | 0.03% | 98% |
| N ₂ | - | 78% | 1.9% |
| O ₂ | - | 21% | trace |

Estimated surface temperature: 290°C

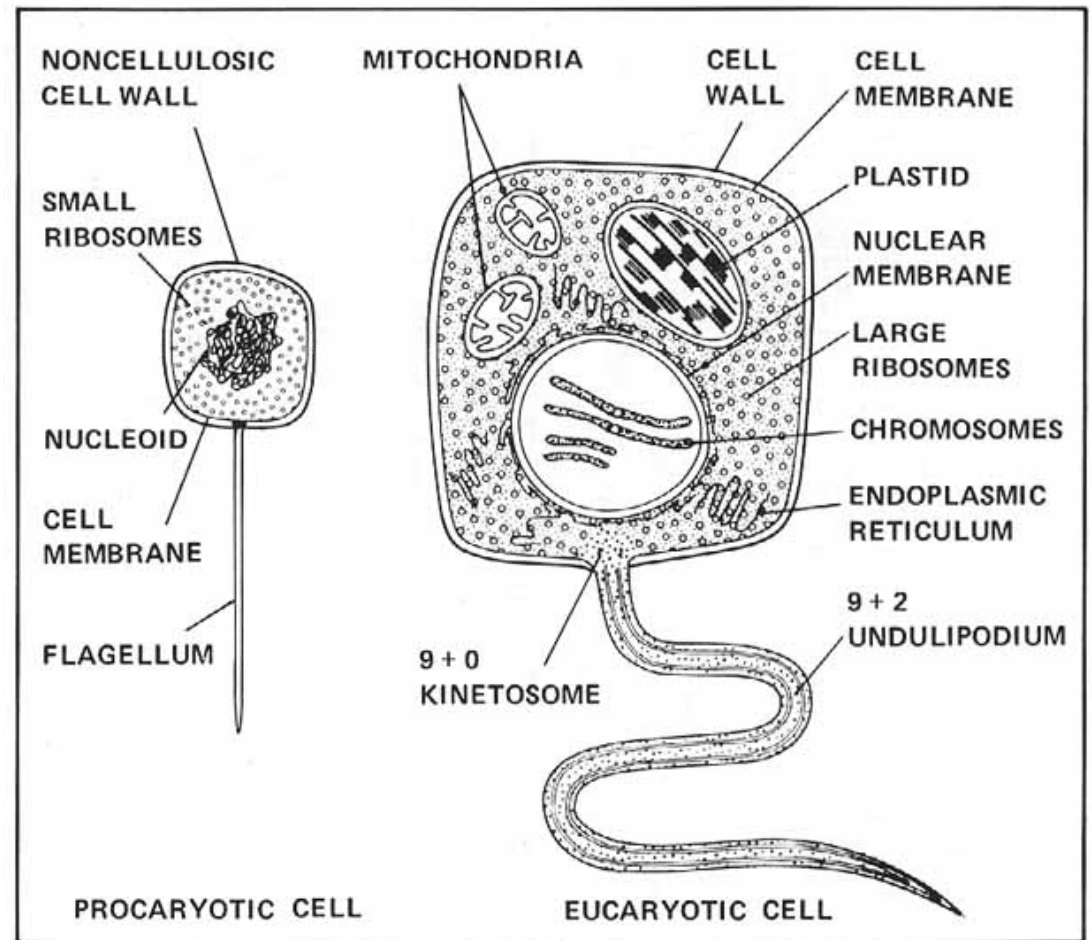

Estimated growth of free oxygen in the Earth's atmosphere

Complex life forms on Earth have complex cell structures including specialized structures called organelles.

Most organelles contain their own genetic code, and reproduce independently of the cell.

The leading theory on how these came about is Lynn Margulis's **endosymbiotic theory**.

<http://history.nasa.gov/>

RUBBING ELBOWS

WITH **NEWTON,
COPERNICUS,
AND EINSTEIN**

<http://www.umass.edu/synergy>

Basic idea: The organelles used to be free living single celled organisms, but over time were incorporated into larger single celled organisms, and symbiosis co-evolved.

FIGURE 3.3 Evolution of eukaryotic cells by a series of endosymbiotic events: (1) mitochondria evolve from small, free-living, respiring bacteria; (2) the nucleus evolves from the simpler prokaryotic DNA molecule; (3) flagella (undulipodia) evolve from symbiotic spirochetes; (4) chloroplasts arise from free-living cyanobacteria. Cell walls in plants and fungi, which are structurally quite different, evolve independently.

<http://www.msu.edu/course/lbs/>

EUKARYA

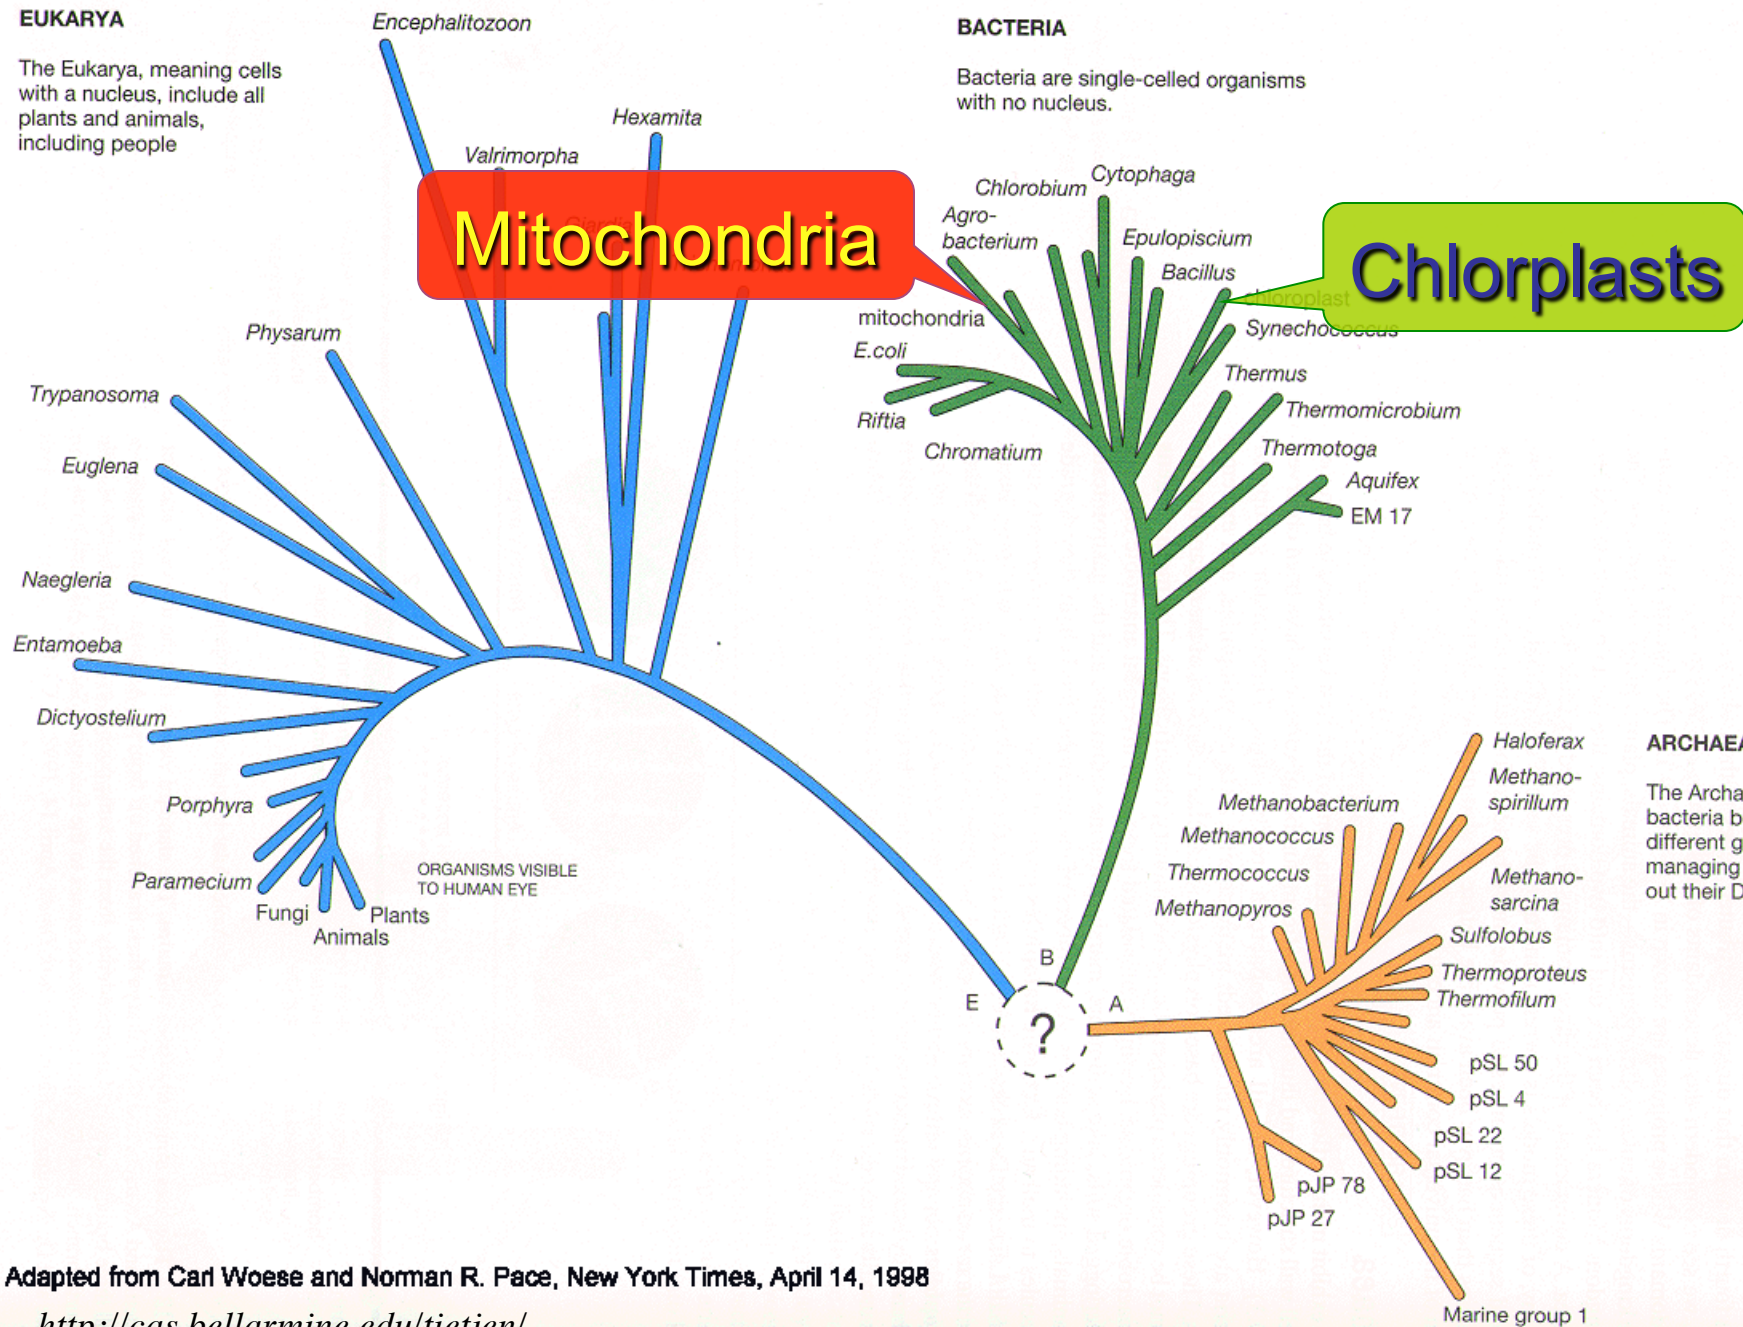

The Eukarya, meaning cells with a nucleus, include all plants and animals, including people

BACTERIA

Bacteria are single-celled organisms with no nucleus.

ARCHAEA

The Archaea look like bacteria but have different genes for managing and reading out their DNA.

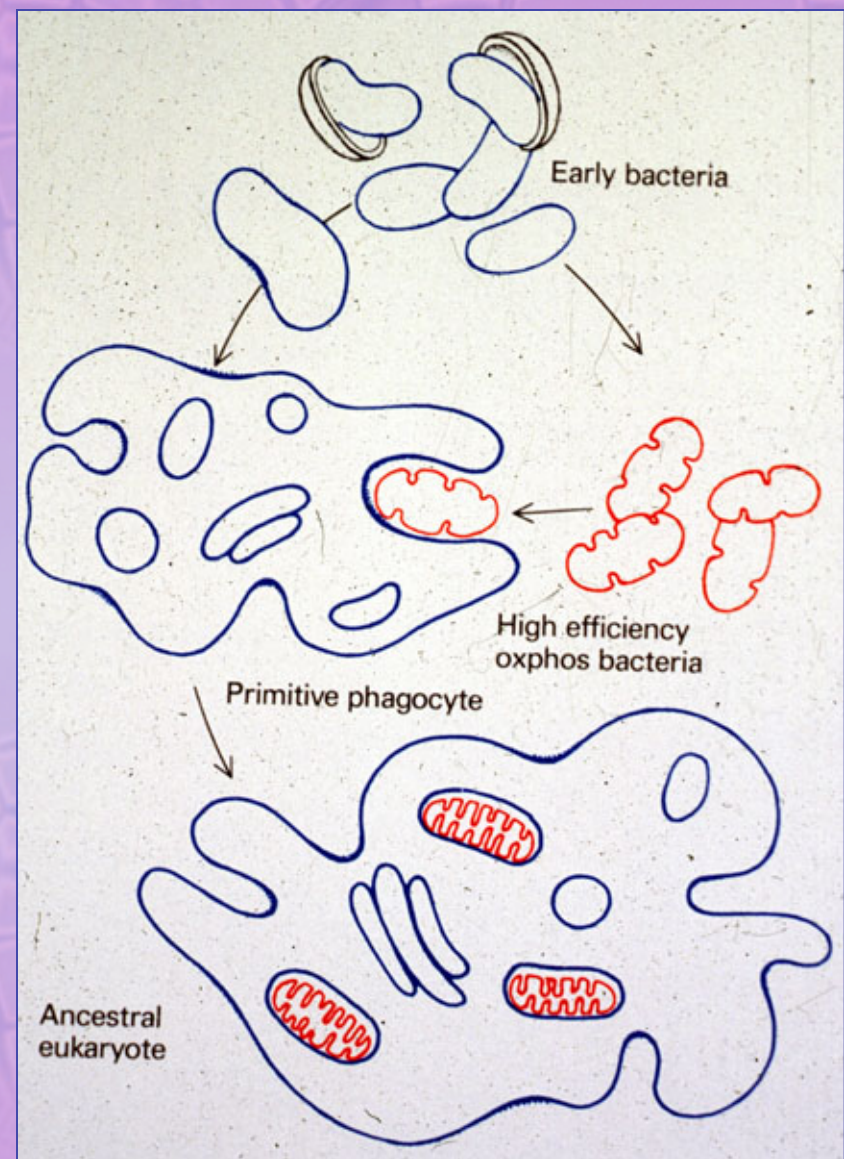

Adapted from Carl Woese and Norman R. Pace, New York Times, April 14, 1998

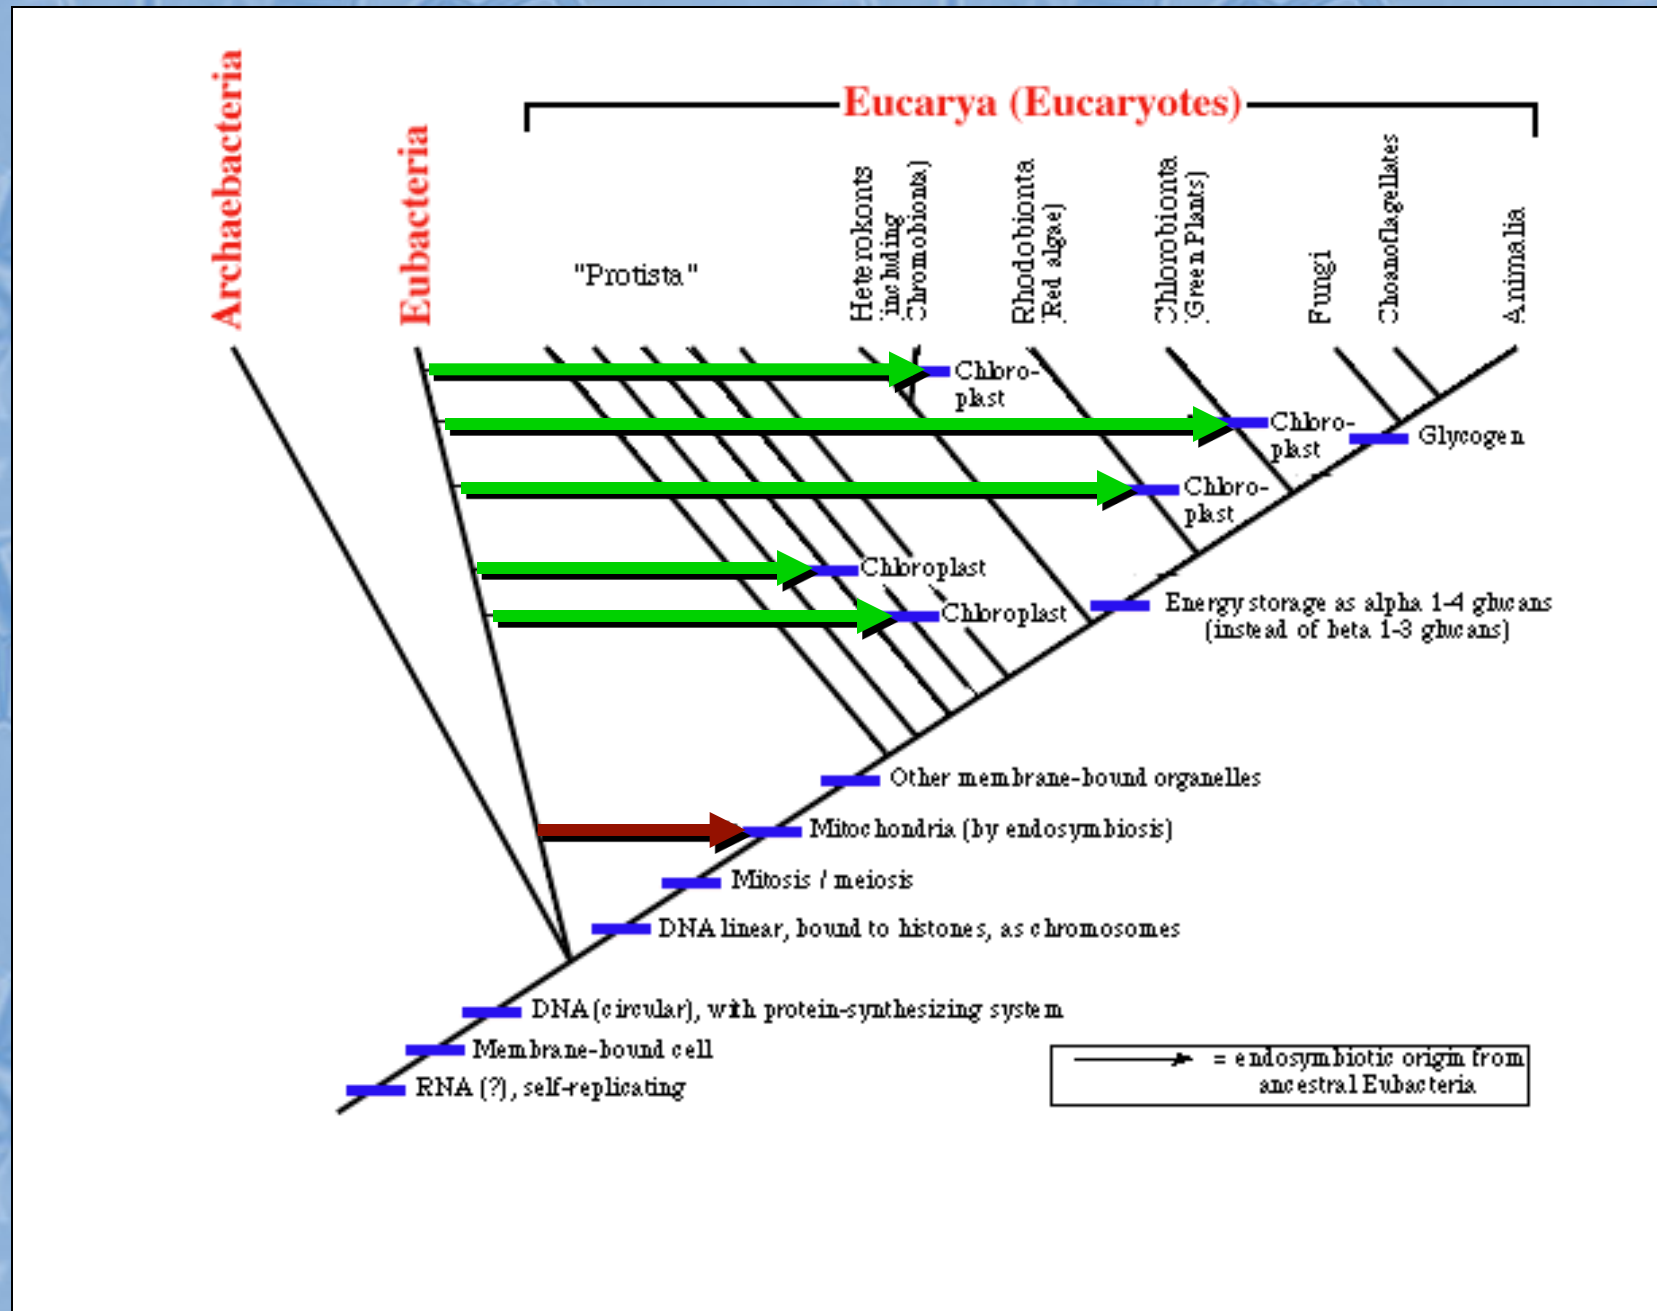

<http://cas.bellarmine.edu/tietjen/>

The incorporated bacteria all have a “skill” (e.g., efficient protein production, photosynthesis, or locomotion) that would be of benefit to a potential phagocyte (cell-eater).

By incorporating the foreign cells instead of digesting them, the cell gains these skills.

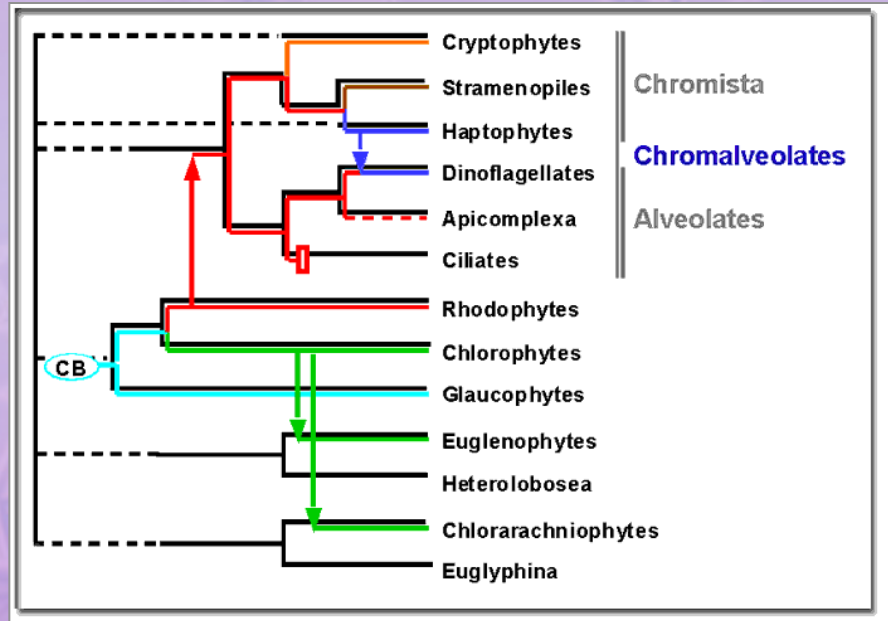

Natural selection should tend to favor the evolution of efficient working relationships through co-evolution of host and guest.

Secondary Endosymbiosis

(eukaryotes absorbing other eukaryotes!)

Metazoans

Includes all animals, including sponges (Philippe et al 2009)

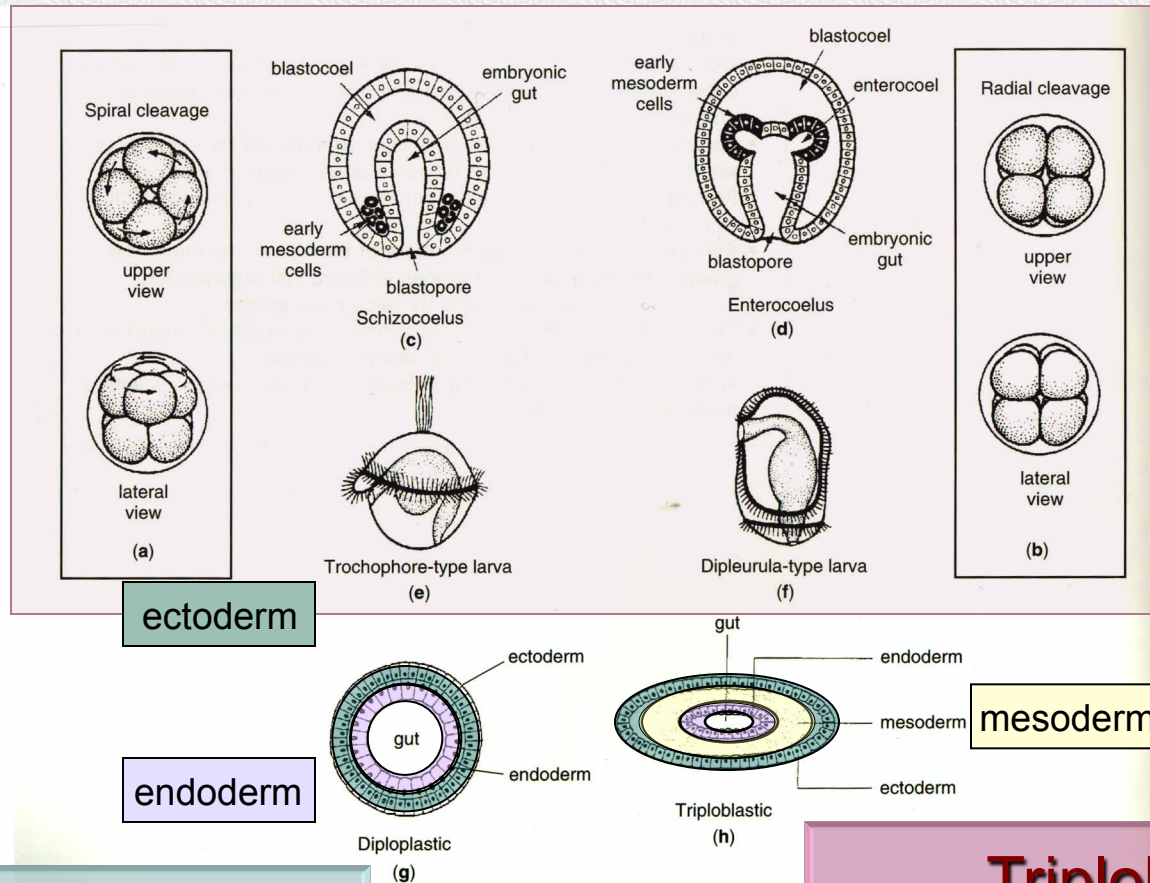

All phyla except sponges have organized tissues and a nerve cells.

Among other traits, “advanced” metazoans are distinguished by their embryonic development.

Most metazoan phyla consist of worms, which are rarely preserved as fossils.

Metazoan Embryonic Development

ectoderm

endoderm

mesoderm

Diploblastic

Two embryonic cell layers:

- ectoderm
- endoderm

Triploblastic

Three embryonic cell layers:

- ectoderm
- mesoderm
- endoderm

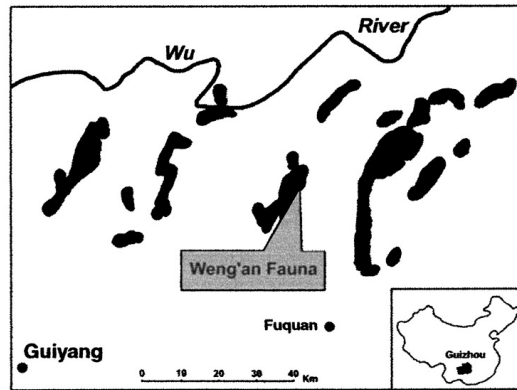

Shuhai Zhao

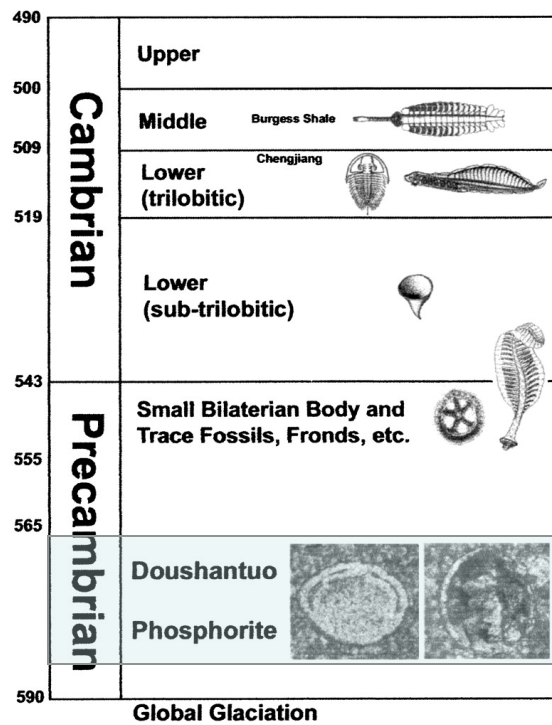

Education: University of Beijing,
Harvard University

Current Position: Virginia Tech

Discovered fossil embryos (and other fossils) in the Precambrian strata of China - specifically in the **Doushantuo Formation** (~575 Ma).

Vendian/Ediacaran Fauna

So what *were* these things?

- The most popular view is that these were the first large metazoans, and that at least some are ancestral to animal phyla.
- A now discredited hypothesis is that they were early fungi.
- A minority view is the “Garden of Ediacara” theory.
